1 INTRODUCTION

Given a projective algebraic variety $X$ in the $N$-dimensional projective space $\mathbb{P}^N_k$ over an algebraically closed field $k$, we can associate to $X$ its Hilbert function, viz., the function $h: \mathbb{N} \rightarrow \mathbb{N}$ defined on the set $\mathbb{N}$ of nonnegative integers by $h(\ell) = \dim_k R_{\ell}$, for $\ell \in \mathbb{N}$ where $R$ denotes the homogeneous coordinate ring of $X$, i.e., $R$ is the polynomial ring over $k$ in $N+1$ variables modulo the vanishing ideal of $X$, and $R_{\ell}$ denotes its $\ell$–th homogeneous component. It is well-known that $h(\ell)$ is a polynomial function, for all large enough values of $\ell$, and this polynomial, called the Hilbert polynomial of $X$, contains a lot of useful geometric information about $X$. However, the Hilbert polynomial is not always easy to compute explicitly in substantial examples of geometric interest. Classically, the known cases seem only to include simple examples such as hypersurfaces, rational normal curves, and more generally, complete intersections. Recently, Hilbert polynomials of determinantal varieties of various kinds, have been explicitly determined [1, 2, 5, 7]. However some of these formulae are quite complicated.

Schubert varieties in Grassmannians form an important class of projective varieties, which have been considered at least since the last century. A nice, short and explicit formula for the Hilbert polynomial of such a variety, known as the postulation formula, was obtained by Hodge [9] in 1943. We feel that this formula...
deserves to be better known, especially since it arises in a number of seemingly
different contexts, particularly in Combinatorics. Partly motivated by this desire,
we describe in this note the formula of Hodge, derive a slightly simpler description
of it and give an alternate proof of the formula. This will also provide us with
an opportunity to briefly introduce combinatorics of nonintersecting lattice paths,
which, in the same vein, deserves to be better known among the algebraists.

The basic facts needed about Schubert varieties in Grassmannians are described
in the next section. We review some combinatorial facts about lattice paths in
Section 3. Finally, a proof of the postulation formula is given in Section 4.

## 2 SCHUBERT VARIETIES IN GRASSMANNIANS

Let $k$ be a field, which, for simplicity, we assume to be algebraically closed. Let $V$
be a vector space of dimension $n$ over $k$. Given any integer $d$ with $1 \leq d \leq n$,
the Grassmannian $G_d(V)$ is defined to be the space of $d$-dimensional linear subspaces
of $V$. This has a canonical embedding

$$G_d(V) \hookrightarrow \mathbb{P}(\Lambda^d V) \simeq \mathbb{P}^{\binom{n}{d}-1}_k$$

known as the Plücker embedding, and via this embedding $G_d(V)$ has the structure
of a projective algebraic variety. Briefly, the Plücker embedding may be described
as follows. Fix a basis $\{e_1, \ldots, e_n\}$ of $V$. Then

$$e_\alpha := e_{\alpha_1} \wedge \cdots \wedge e_{\alpha_d},$$

where $\alpha$ varies over the indexing set

$$I(d, n) = \{\alpha = (\alpha_1, \ldots, \alpha_d) \in \mathbb{Z}^d : 1 \leq \alpha_1 < \cdots < \alpha_k \leq n\}$$

form a basis of $\Lambda^d V$. The image of a subspace $W \in G_d(V)$ is the point of $\mathbb{P}(\Lambda^d V)$
corresponding to the one-dimensional subspace of $\Lambda^d V$ spanned by $w_1 \wedge \cdots \wedge w_d$,
where $\{w_1, \ldots, w_d\}$ is (any) basis of $W$. If we write

$$w_1 \wedge \cdots \wedge w_d = \sum_{\alpha \in I(d, n)} p_\alpha(W)e_\alpha,$$

then $p(W) = (p_\alpha(W))_{\alpha \in I(d, n)}$ is called the Plücker coordinate of $W$.

Given any $\alpha = \in I(d, n)$, the corresponding Schubert variety $\Omega_\alpha$ is defined by

$$\Omega_\alpha = \{W \in G_d(V) : \dim(W \cap A_i) \geq i \text{ for } i = 1, \ldots, d\},$$

where $A_i = \text{span}\{e_1, \ldots, e_{\alpha_i}\}$ for $1 \leq i \leq d$. We have a partial order, called the Bruhat order, on the indexing set $I(d, n)$, which is defined by

$$\beta \leq \beta' \iff \beta_j \leq \beta'_j \text{ for all } j = 1, \ldots, d,$$

where $\beta = (\beta_1, \ldots, \beta_d)$ and $\beta' = (\beta'_1, \ldots, \beta'_d)$ are arbitrary elements of $I(d, n)$. Using this, we can describe $\Omega_\alpha$ in terms of the Plücker coordinates as follows.

$$\Omega_\alpha = \{p = (p_\alpha) \in G_d(V) : p_\beta = 0 \text{ for all } \beta \in I(d, n) \text{ with } \beta \not\leq \alpha\}.$$
Hence, $\Omega_\alpha$ is also a projective algebraic variety. In fact, $\Omega_\alpha$ is irreducible and
\[
\dim \Omega_\alpha = \sum_{i=1}^{d} \alpha_i - \frac{d(d+1)}{2}.
\]
Note that $G_d(V)$ is a particular case of $\Omega_\alpha$ with $\alpha = (n-d+1, n-d+2, \ldots, n)$. In particular, $\dim G_d(V) = d(n-d)$. For proofs of the basic results mentioned above as well as for a more leisurely discussion, we refer to Hodge and Pedoe’s book [10] or the expository article of Kleiman and Laksov [12].

We shall now turn our attention to the structure of the homogeneous coordinate ring of Schubert varieties. Let $P = \{ P_\gamma : \gamma \in I(d, n) \}$ be a family of independent indeterminates over $k$ and $k[P]$ be the ring of polynomials in these indeterminates with coefficients in $k$. Fix $\alpha \in I(d, n)$, and let $I(\Omega_\alpha)$ denote the (vanishing) ideal of $\Omega_\alpha$. This is a homogeneous ideal of $k[P]$ and thus the residue class ring $R_\alpha = k[P]/I(\Omega_\alpha)$ has a natural graded ring structure. For $\ell \in \mathbb{N}$, let $R_\alpha^\ell$ denote the $\ell$-th graded component of $R_\alpha$. Also let $p_\gamma$ denote the image of $P_\gamma$ in $R_\alpha$. By a standard monomial on $\Omega_\alpha$ we mean an element of $R_\alpha$ of the form $p_{\gamma_1} p_{\gamma_2} \cdots p_{\gamma_\ell}$, where $\gamma_1, \ldots, \gamma_\ell$ are elements of $I(d, n)$ with the property that $\gamma_1 \leq \cdots \leq \gamma_\ell \leq \alpha$. The number of terms, i.e., $\ell$, is called the degree of this monomial. Now we have the following basic result.

**Theorem 1** The standard monomials on $\Omega_\alpha$ form a vector space basis of $R_\alpha$. More precisely, for each $\ell \in \mathbb{N}$, the standard monomials on $\Omega_\alpha$ of degree $\ell$ form a vector space basis of $R_\alpha^\ell$.

Observe that a standard monomial on $\Omega_\alpha$ of degree $\ell$ is completely determined by a $\ell \times d$ rectangular array $(a_{ij})$ of integers with the property that
\[
1 \leq a_{i1} < \cdots < a_{id} \quad \text{for} \quad 1 \leq i \leq \ell \quad \text{and} \quad a_{ij} \leq \cdots \leq a_{\ell j} \leq \alpha_j \quad \text{for} \quad 1 \leq i \leq d. \quad (1)
\]
We shall refer to such integral arrays as rectangular standard tableaux bounded by $\alpha$ of size $\ell \times d$. The following corollary is an immediate consequence of the above theorem.

**Corollary 2** The Hilbert function $h_\alpha$ of $\Omega_\alpha$ is given by
\[
h_\alpha(\ell) = \#(\text{rectangular standard tableaux bounded by } \alpha \text{ of size } \ell \times d), \quad \text{for } \ell \in \mathbb{N}.
\]

**Remark 3** The above theorem describing an explicit basis for the homogeneous coordinate ring of Schubert varieties is sometimes called Hodge Basis Theorem. A proof in characteristic zero is given in Hodge and Pedoe [10, Ch. XIV, Sec. 9]. For a characteristic free proof, see, for example, Musili [15]. The Brandeis lecture notes of Seshadri [16] is also a nice readable reference for a proof of this theorem as well as for extensions to the context of Schubert varieties in $G/P$, where $G$ is a nice algebraic group and $P$ a parabolic subgroup.

### 3 Nonintersecting Lattice Paths

Let $A = (a, a')$ and $B = (b, b')$ be points with integer coordinates, i.e., in $\mathbb{Z}^2$. By a lattice path from $A$ to $B$ we mean a finite sequence $L = (P_0, P_1, \ldots, P_m)$ of
points in $\mathbb{Z}^2$ with $P_0 = A$, $P_m = B$ and
$$P_i - P_{i-1} = (1, 0) \text{ or } (0, 1) \quad \text{for } i = 1, \ldots, m.$$ 
Note that the lattice path $L$ is determined by its point set $\bar{L} = \{P_j : 0 \leq j \leq m\}$ by simply arranging the elements of this set in a lexicographic order.

In more intuitive terms, a lattice path consists of vertical or horizontal steps of length 1. For example, a lattice path from $A = (1, 1)$ to $B = (5, 6)$ may be depicted as follows.

![Figure 1](image)

It is clear that a lattice path from $A$ to $B$ would require $b - a$ vertical steps and $b' - a'$ horizontal steps, and it would be determined once we choose which of the total $b - a + b' - a'$ (ordered) steps are vertical. Thus,
$$\# \text{ (lattice paths from } A \text{ to } B) = \binom{b - a + b' - a'}{b - a}. \quad (2)$$

Note that this number is positive if and only if $b \geq a$ and $b' \geq a'$.

Given any two $d$-tuples $A = (A_1, \ldots, A_d)$ and $B = (B_1, \ldots, B_d)$ of points in $\mathbb{Z}^2$, by a $d$-path, or simply, a path, from $A$ to $B$ we mean a $d$-tuple $L = (L_1, \ldots, L_d)$ where $L_r$ is a lattice path from $A_r$ to $B_r$, for $1 \leq r \leq d$. We call $L$ to be nonintersecting if no two of the paths $L_1, \ldots, L_d$ have a point in common; otherwise, we call it intersecting. For counting the number of nonintersecting lattice paths, we have the following beautiful result.

**THEOREM 4** Let $A_r = (a_r, a'_r)$ and $B_r = (b_r, b'_r)$, $r = 1, \ldots, d$, be points in $\mathbb{Z}^2$ satisfying
$$a_1 \geq \ldots \geq a_d, \quad b_1 \geq \ldots \geq b_d \quad \text{and} \quad a'_1 \leq \ldots \leq a'_d, \quad b'_1 \leq \ldots \leq b'_d. \quad (3)$$

Let $A = (A_1, \ldots, A_d)$ and $B = (B_1, \ldots, B_d)$. Then the number of nonintersecting paths from $A$ to $B$ is equal to the binomial determinant
$$\det \left( \begin{pmatrix} b_j - a_i + b'_j - a'_i \\ b_j - a_i \end{pmatrix} \right)_{1 \leq i, j \leq d}. \quad (4)$$
In other words, this is the determinant of a \( d \times d \) matrix whose \((i,j)\)-th entry is the number of lattice paths from \( A_i \) to \( B_j \).

The idea behind the proof is quite simple and elegant. Let us illustrate in the case \( d = 2 \). So let \( \mathcal{A} = (A_1, A_2) \) and \( \mathcal{B} = (B_1, B_2) \), with \( A_i, B_i \) as in Theorem 4. From (2) it is clear that

\[
\# \text{(lattice paths from } \mathcal{A} \text{ to } \mathcal{B}) = \left( \frac{b_1 - a_1 + b'_1 - a'_1}{b_1 - a_1} \right) \left( \frac{b_2 - a_2 + b'_2 - a'_2}{b_2 - a_2} \right).
\]

(5)

If a path \( \mathcal{L} = (L_1, L_2) \) from \( \mathcal{A} \) to \( \mathcal{B} \), where \( L_1 = (P_0, \ldots, P_s) \) and \( L_2 = (Q_0, \ldots, Q_t) \) is intersecting, then we can find least \( i \geq 0 \) such that \( P_i = Q_j \) for some \( j \leq t \). Now switch the paths at \( P_i = Q_j \), i.e., consider \( L'_1 = (P_0, \ldots, P_i, Q_j+1, \ldots, Q_t) \) and \( L'_2 = (Q_0, \ldots, Q_j, P_{i+1}, \ldots, P_s) \). In this way we get a path from \( (A_1, A_2) \) to \( (B_2, B_1) \). Conversely, by (3), any path from \( (A_1, A_2) \) to \( (B_2, B_1) \) must intersect, and a similar switching yields an intersecting path from \( \mathcal{A} \) to \( \mathcal{B} \). Thus one obtains a bijection which shows that

\[
\# \text{(intersecting paths from } \mathcal{A} \text{ to } \mathcal{B}) = \left( \frac{b_2 - a_1 + b'_2 - a'_1}{b_2 - a_1} \right) \left( \frac{b_1 - a_2 + b'_1 - a'_2}{b_1 - a_2} \right).
\]

The last equation together with (5) implies the formula (4) in the case \( d = 2 \).

In the general case, one considers permutations \( \sigma \) of \( \{1, \ldots, d\} \) and the set

\[
\mathcal{P}_\sigma = \{ \mathcal{L} = (L_1, \ldots, L_d) : \text{ } \text{L}_r \text{ is a lattice path from } A_r \text{ to } B_{\sigma(r)} \text{ for } 1 \leq r \leq d \}.
\]

By a similar switching trick, one can obtain an involution \( \phi \) on the set of pairs \((\sigma, \mathcal{L})\), where \( \sigma \in S_d, \mathcal{L} \in \mathcal{P}_\sigma \) and \( \mathcal{L} \) is intersecting, such that if \( \phi ((\sigma, \mathcal{L})) = (\sigma', \mathcal{L}') \), then \( \text{sgn}(\sigma') = -\text{sgn}(\sigma) \). Now, expanding the determinant in (4), and using (2), we see that (4) can be written as

\[
\sum_{\sigma \in S_d} \text{sgn}(\sigma) \sum_{\mathcal{L} \in \mathcal{P}_\sigma} 1 = \sum_{\sigma \in S_d, \mathcal{L} \in \mathcal{P}_\sigma, \mathcal{L} \text{ nonintersecting}} \text{sgn}(\sigma) + \sum_{\sigma \in S_d, \mathcal{L} \in \mathcal{P}_\sigma, \mathcal{L} \text{ intersecting}} \text{sgn}(\sigma).
\]

Thanks to the sign-reversing involution \( \phi \), the terms in the last summation cancel each other, whereas by (3), a path \( \mathcal{L} \in \mathcal{P}_\sigma \) can only be nonintersecting when \( \sigma \) is the identity permutation. Thus the right hand side is the number of nonintersecting paths from \( \mathcal{A} \) to \( \mathcal{B} \), and we have the desired formula.

REMARK 5 The above result is due to Gessel and Viennot [4] though the ideas can perhaps be traced to the works of Karlin-McGregor [11] and Lindstorm [14]. In [4] the endpoints \( A_i, B_i \) are of a more restrictive nature, but the arguments in the proof remain similar.

4 HODGE’S POSTULATION FORMULA

Fix positive integers \( d, n \) with \( d \leq n \) and \( \alpha = (\alpha_1, \ldots, \alpha_d) \in I(d, n) \). Let \( \Omega_\alpha \) denote, as before, the Schubert variety corresponding to \( \alpha \) in the Grassmannian
of $d$-dimensional linear subspaces of an $n$-dimensional vector space over $k$. The postulation formula of Hodge [10, Thm. III, p. 387], in our notation, can be stated as follows.

**THEOREM 6** The Hilbert function of $\Omega_\alpha$ is given by

$$h_\alpha(\ell) = \det \left( \begin{array}{c} \alpha_{d-i+1} + \ell + i - j - 1 \\
\ell + i - j \end{array} \right)_{1 \leq i, j \leq d} \quad \text{for } \ell \in \mathbb{N}. $$

In particular, the Hilbert polynomial of $\Omega_\alpha$ equals the Hilbert function for all non-negative integral values of the parameter $\ell$.

An alternate description of this formula is provided by the following lemma.

**LEMMA 7** Given any $\ell \in \mathbb{N}$, we have

$$\det \left( \begin{array}{c} \alpha_{d-i+1} + \ell + i - j - 1 \\
\ell + i - j \end{array} \right)_{1 \leq i, j \leq d} = \det \left( \begin{array}{c} \ell + \alpha_j - j \\
\ell + i - j \end{array} \right)_{1 \leq i, j \leq d}. $$

**Proof:** If $(b_{i,j})$ is any $d \times d$ matrix, then by a cyclic permutation of the rows (or alternatively, by successive row interchanges) we can transform it to the $d \times d$ matrix whose $(i,j)$-th entry is $b_{d-i+1,j}$, This will change the sign of $\det (b_{i,j})$ by $(-1)^d(d-1)/2$. We can also do a similar operation on the columns. Combining these two, we see that $\det (b_{i,j}) = \det (b_{d-i+1,d-j+1})$. In particular, we have

$$\det \left( \begin{array}{c} \alpha_{d-i+1} + \ell + i - j - 1 \\
\ell + i - j \end{array} \right)_{1 \leq i, j \leq d} = \det \left( \begin{array}{c} \alpha_i + \ell - i + j - 1 \\
\ell - i + j \end{array} \right)_{1 \leq i, j \leq d}. $$

Now for the $d \times d$ matrix corresponding to the determinant on the right hand side of the above equation, we successively make the $n-1$ elementary column operations $C_n - C_{n-1}, C_{n-1} - C_{n-2}, \ldots, C_2 - C_1$. Then in view of the Pascal triangle identity

$$\binom{s}{t} - \binom{s-1}{t-1} = \binom{s-1}{t},$$

the $(i,j)$-th entry changes from $\binom{\alpha_i + \ell - i + j - 1}{\ell - i + j}$ to $\binom{\alpha_i + \ell - i + j - 2}{\ell - i + j}$, for $j \geq 2$, while the determinant is unaltered. Next, we make the $n-2$ elementary column operations $C_n - C_{n-1}, C_{n-1} - C_{n-2}, \ldots, C_3 - C_2$, and continue in this way till in the end we just make a single column operation $C_n - C_{n-1}$. In this process the $j$-th column of the original matrix is altered $j - 1$ times, and its entries eventually become

$$\binom{\alpha_i + \ell - i + j - 1 - (j - 1)}{\ell - i + j} = \binom{\alpha_i + \ell - i}{\ell - i + j}. $$

By taking the transpose of the resulting matrix, we have the desired formula. \qed

We will now link the rectangular standard tableaux appearing in Corollary 2 to nonintersecting paths. The idea to associate such a path to a rectangular tableaux $(a_{i,j})$ is quite simple. Start at $(1, 1)$. Move vertically till $(1, a_{11})$. Go one step to
Proof: Let \((\alpha_{ij})\) be a rectangular standard tableau bounded by \(\alpha\) of size \(\ell \times d\). As a convention, we set, \(a_{0j} = j\) and \(a_{i+1} = \alpha_j\) for \(1 \leq j \leq d\). By (1), it is clear that \(a_0 \leq a_{ij} \leq \cdots \leq a_{ij} \leq \alpha_{i+1,j}\) for each \(j = 1, \ldots, d\). For \(1 \leq r \leq d\), define \(L_r\) to be the lattice path from \(A_r\) to \(B_r\) whose point set is given by

\[
L_r = \{(i - r + 1, j) : 1 \leq i \leq r + 1 \text{ and } a_{i-1} \leq j \leq a_{ir}\}
\]

It is easy to see that \(L_r\) is well-defined. Moreover, if for \(1 \leq r, s \leq d\), \(r \neq s\), the lattice paths \(L_r\) and \(L_s\) intersect, then we have \((i_1 - r + 1, j_1) = (i_2 - s + 1, j_2)\) for appropriate \(i_1, i_2, j_1, j_2\), and if, without loss of generality, we have \(r < s\), then \(i_1 \leq i_2 - 1\) and hence \(j_2 = j_1 \leq a_{ir} \leq a_{ir} - 1 < a_{i-1} - 1\), which is a contradiction. Thus \(L = (L_1, \ldots, L_d)\) is a nonintersecting \(d\)-path from \(A\) to \(B\).

Conversely, let \(L = (L_1, \ldots, L_d)\) be a nonintersecting \(d\)-path from \(A\) to \(B\). Given \(1 \leq r \leq d\), the fact that \(L_r\) is a lattice path implies that for \(1 \leq i \leq \ell\), we have

\[
\max\{j \in \mathbb{N} : (i - r + 1, j) \in L_r\} = \min\{j \in \mathbb{N} : (i - r + 2, j) \in L_r\};
\]

let \(a_{ir}\) be this common value. In this way we get a \(\ell \times d\) array \((\alpha_{ij})\) of integers. Since \(L_r\) is a lattice path from \(A_r\) to \(B_r\), we have \(1 \leq a_{ir} \leq a_{i+1, r} \leq \alpha_r\) for \(1 \leq i \leq \ell\). Further, if \(a_{ir} \geq a_{i+1, r}\), then it is clear that the truncated paths \(L_r\) and \(L_{r+1}\) obtained respectively by moving along \(L_r\) and \(L_{r+1}\) till \((i - r + 1, a_{ir})\) and \((i - r + 2, a_{ir+1})\), must intersect. This contradicts the assumption that \(L\) is nonintersecting. It follows that the array \((\alpha_{ij})\) satisfies the properties in (1).

In this way we get a map from the set of nonintersecting \(d\)-paths from \(A\) to \(B\) to the set of rectangular standard tableaux bounded by \(\alpha\) of size \(\ell \times d\), and vice-versa. It is easy to see that the composites, either way, are identity maps.

Proof of Theorem 6: Follows from Corollary 2, Theorem 4 and Lemmas 7 and 8. □

REMARK 9 It may be remarked that the above proof of Hodge’s postulation formula is structurally analogous to the proof given in [2] and [6] for determining the Hilbert function and Hilbert series of certain determinantal ideals. The correspondence between the standard bitableaux appearing there and nonintersecting lattice paths (with a given number of turns) was somewhat more intricate, i.e., first one had to use a version of the Robinson-Schensted-Knuth correspondence and then something like Viennot’s light-and-shadow procedure. Here, as Lemma 8 shows, we can use a more direct correspondence. On the other hand, it does not appear easy to find a ‘good formula’ for the Hilbert series of \(\Omega_n\). Connection with lattice paths has also been exploited in [8] to prove a formula for the multiplicity of
determinantal ideals. Hodge’s postulation formula, and particularly the unusual
fact that the Hilbert function \( h_\alpha(\ell) \) is a polynomial for all values of \( \ell \) was in fact,
the starting point of the investigations by Musili [15], which led to certain van-
ishing theorems for Schubert varieties in Grassmannians. These results have now
been vastly generalized (see [13] for a survey) while a far-reaching generalization of
Hodge’s postulation formula itself has been obtained by Fulton and Lascoux [3].
